

#### **Unsupervised Learning: Clustering**

Nicholas Ruozzi
University of Texas at Dallas

#### **Announcements**

- Midterm (next Monday in class)
  - Closed book, closed notes, etc. (just you and a pencil)
  - Try to arrive as early as possible so as to maximize your exam taking time
  - Covers everything up to the end of boosting
  - Be prepared for theoretical questions!
  - The exam is worth a significant percentage of the grade, talk to other students and use Piazza to make sure that you are prepared!

#### **Announcements**

- Homework 1 & 2 grades are now available
  - Talk to the TA about any grading issues/questions
- Solutions will be posted soon
- Homework 3: will be due on 10/19, but you should attempt it before the exam

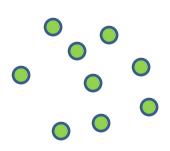

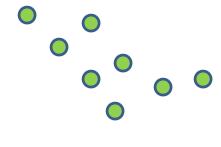

#### **Clustering systems:**

- Unsupervised learning
- Requires data, but no labels
- Detect patterns, e.g., in
  - Group emails or search results
  - Customer shopping patterns
- Useful when don't know what you're looking for
  - But often get gibberish

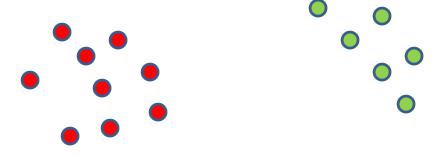

- Want to group together parts of a dataset that are close together in some metric
  - Useful for finding the important parameters/features of a dataset

- Want to group together parts of a dataset that are close together in some metric
  - Useful for finding the important parameters/features of a dataset

- Intuitive notion of clustering is a somewhat ill-defined problem
  - Identification of clusters depends on the scale at which we perceive the data

- Intuitive notion of clustering is a somewhat ill-defined problem
  - Identification of clusters depends on the scale at which we perceive the data

• Input: a collection of points  $x_1, ..., x_n \in \mathbb{R}^m$ , an integer k

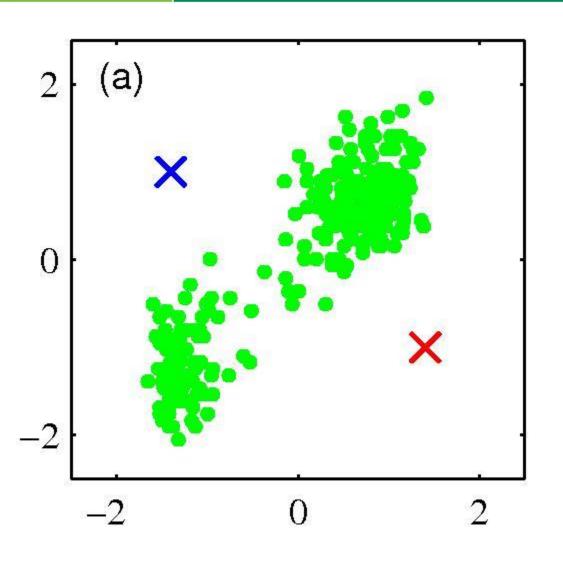

• Output: A partitioning of the input points into k sets that minimizes some metric of closeness

## k-means Clustering

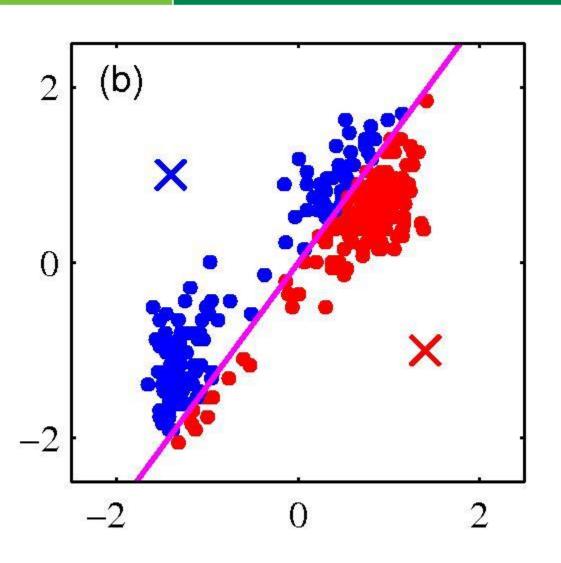

- Pick an initial set of k means (usually at random)
- Repeat until the clusters do not change:
  - Partition the data points, assigning each data point to a cluster based on the mean that is closest to it
  - Update the cluster means so that the  $i^{th}$  mean is equal to the average of all data points assigned to cluster i

Pick *k* random points as cluster centers (means)

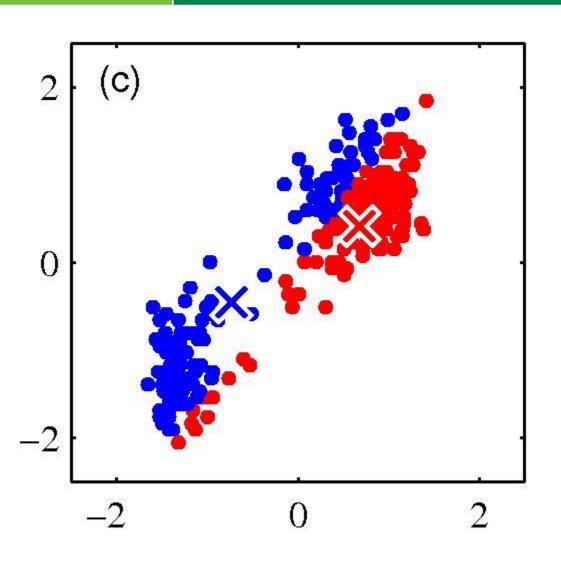

#### **Iterative Step 1:**

Assign data instances to closest cluster center

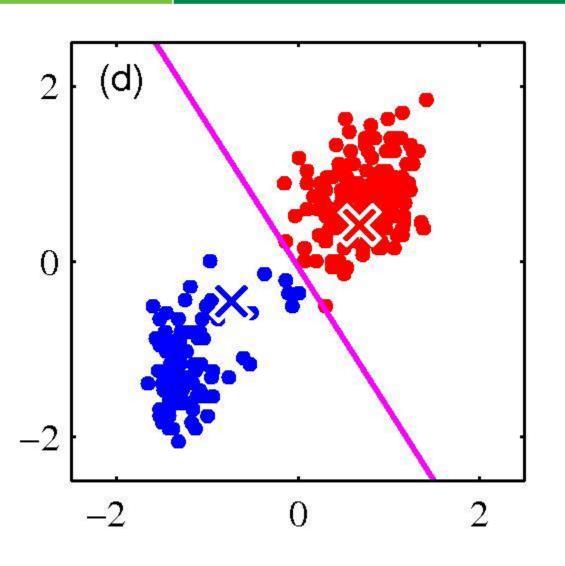

#### **Iterative Step 2:**

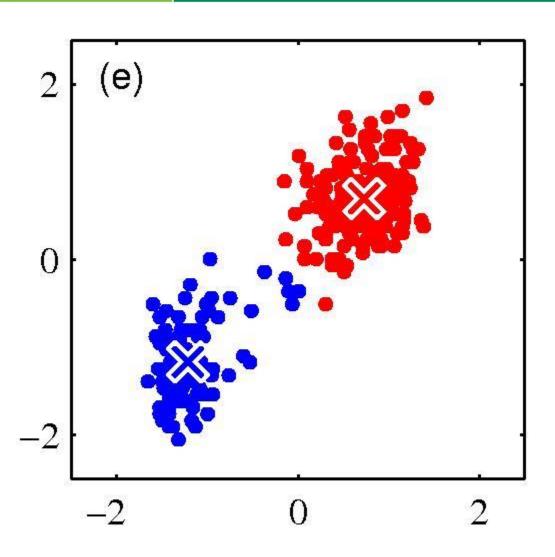

Change the cluster center to the average of the assigned points

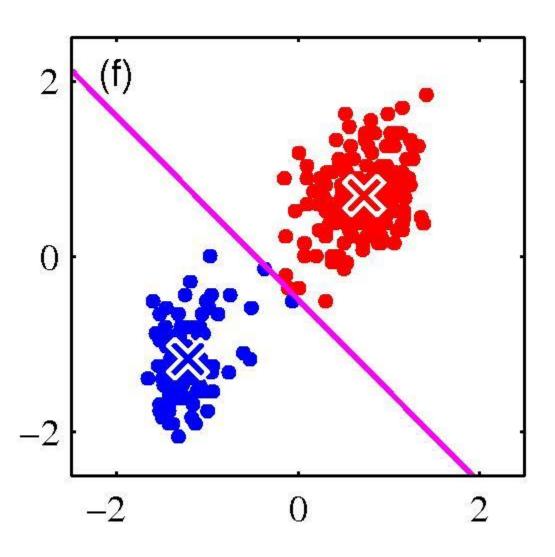

Repeat until convergence

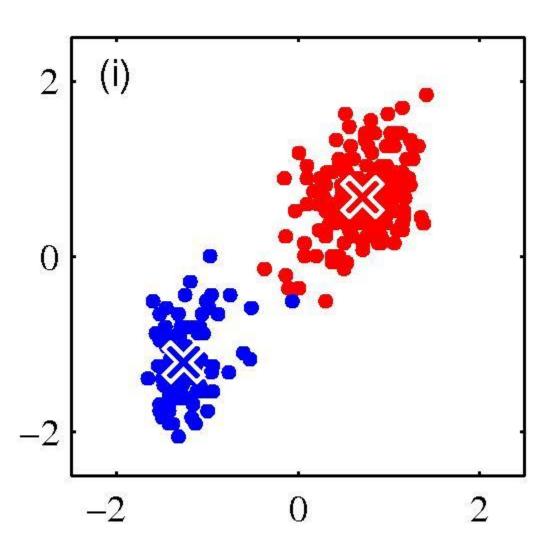

#### k-Means for Segmentation

Goal of Segmentation is to partition an image into regions each of which has reasonably homogenous visual appearance

#### k-Means for Segmentation

k = 3

Original

#### k-Means for Segmentation

k = 3

k = 10

Original

#### k-means Clustering as Optimization

 Minimize the distance of each input point to the mean of the cluster/partition that contains it

$$\min_{S_1, ..., S_k} \sum_{i=1}^k \sum_{j \in S_i} ||x_j - \mu_i||^2$$

#### where

- $-S_i \subseteq \{1, ..., n\}$  is the  $i^{th}$  cluster
- $-S_i \cap S_j = \emptyset \text{ for } i \neq j, \cup_i S_i = \{1, \dots, n\}$
- $-\mu_i$  is the centroid of the  $i^{th}$  cluster

#### k-means Clustering as Optimization

 Minimize the distance of each input point to the mean of the cluster/partition that contains it

$$\min_{S_1, \dots, S_k} \sum_{i=1}^k \sum_{j \in S_i} ||x_j - \mu_i||^2$$

#### where

Exactly minimizing this function is NP-hard (even for k = 2)

- $-S_i \subseteq \{1, ..., n\}$  is the  $i^{th}$  cluster
- $-S_i \cap S_j = \emptyset \text{ for } i \neq j, \cup_i S_i = \{1, \dots, n\}$
- $-\mu_i$  is the centroid of the  $i^{th}$  cluster

### k-means Clustering

 The k-means clustering algorithm performs a block coordinate descent on the objective function

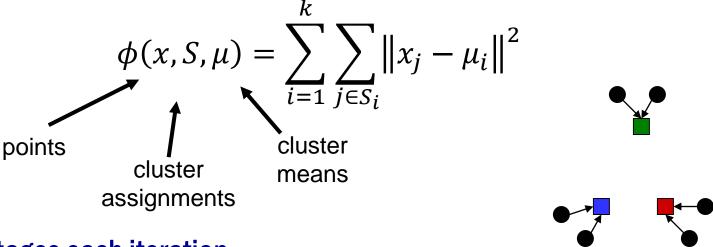

$$\sum_{i=1}^{k} \sum_{j \in S_i} ||x_j - \mu_i||^2$$

• This is not a convex function: could get stuck in local minima

#### k-Means as Optimization

Consider the k-means objective function

- Two stages each iteration
  - Update cluster assignments: fix means  $\mu$ , change assignments S
  - Update means: fix assignments S, change means  $\mu$

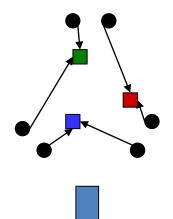

#### Phase I: Update Assignments

• For each point, re-assign to closest mean,  $x^{(j)} \in S_i$  if

$$j \in \arg\min_{i} ||x_j - \mu_i||^2$$

• Can only decrease  $\phi$  as the sum of the distances of all points to their respective means must decrease

$$\phi(x, S, \mu) = \sum_{i=1}^{k} \sum_{j \in S_i} ||x_j - \mu_i||^2$$

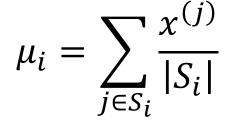

#### **Phase II: Update Means**

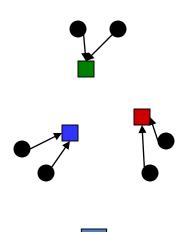

Move each mean to the average of its assigned points

$$\mu_i = \sum_{j \in S_i} \frac{x^{(j)}}{|S_i|}$$

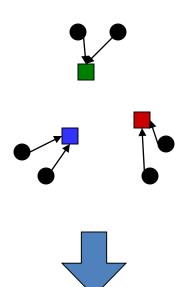

#### **Phase II: Update Means**

Move each mean to the average of its assigned points

$$\mu_i = \sum_{j \in S_i} \frac{x^{(j)}}{|S_i|}$$

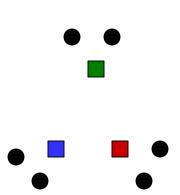

#### **Initialization**

- K-means is sensitive to initialization
  - It does matter what you pick!
  - What can go wrong?

#### **Initialization**

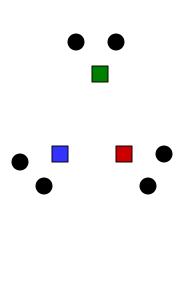

- K-means is sensitive to initialization
  - It does matter what you pick!
  - What can go wrong?

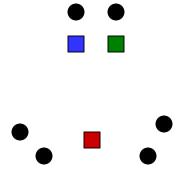

#### **Initialization**

- K-means is sensitive to initialization
  - It does matter what you pick!
  - What can go wrong?
    - Various schemes to help alleviate this problem: initialization heuristics

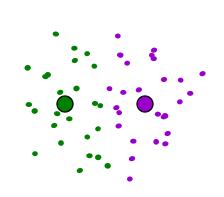

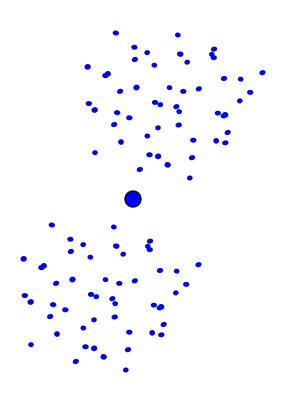

### k-means Clustering

- Not clear how to figure out the "best" k in advance
- Want to choose k to pick out the interesting clusters, but not to over fit the data points
  - Large k doesn't necessarily pick out interesting clusters
  - Small k can result in large clusters than can be broken down further

# **Local Optima**

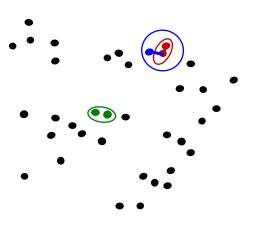

#### k-Means Summary

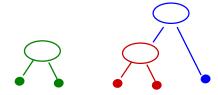

- Guaranteed to converge
  - But not to a global optimum
- Choice of k and initialization can greatly affect the outcome
- Runtime: O(kn) per iteration
- Popular because it is fast, though there are other clustering methods that may be more suitable depending on your data

### **Hierarchical Clustering**

- Agglomerative clustering
  - Incrementally build larger clusters out of smaller clusters
- Algorithm:
  - Maintain a set of clusters
  - Initially, each instance in its own cluster
  - Repeat:
    - Pick the two closest clusters
    - Merge them into a new cluster
    - Stop when there is only one cluster left
- Produces not one clustering, but a family of clusterings represented by a dendrogram

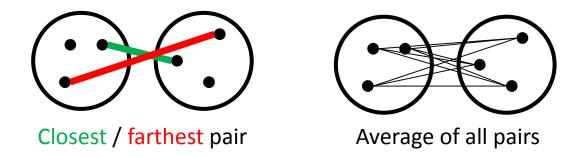

### **Agglomerative Clustering**

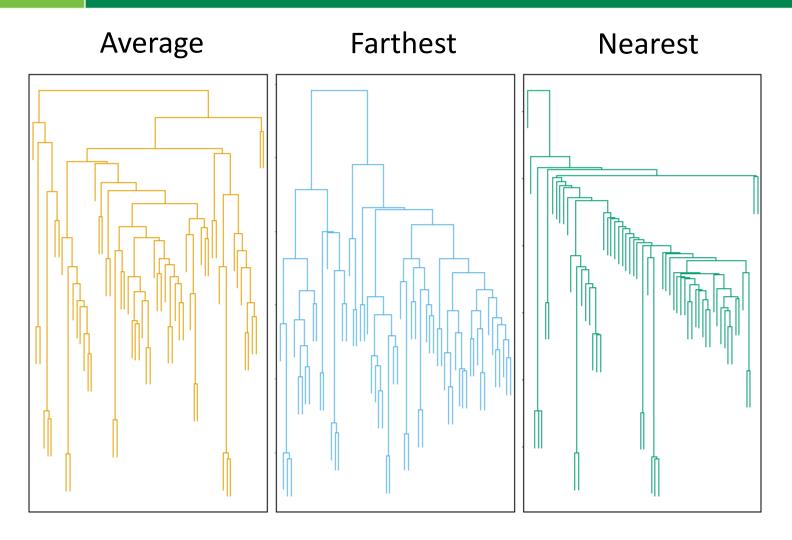

How should we define "closest" for clusters with multiple elements?

Many more choices, each produces a different clustering...

# **Clustering Behavior**

Mouse tumor data from [Hastie]
